SUMMARY

Wheat Outlook Favors a Larger 1979 Crop

Despite the late arrival of spring and planting delays, generally good moisture conditions and expanded acreage favor a 1979 wheat crop above last year's 1.8 billion bushels but short of 1977's 2-billion-bushel crop. Harvest is beginning on a new winter wheat crop that is estimated at 1.39 billion bushels, 11 percent more than last year. Hard Red Winter acreage is slightly larger but Soft Red Winter producers seeded a fourth more than the abnormally small 1978 crop. Growers intend to increase 1979 spring wheat acreage by 4 percent, but late snow melt accompanied by wet soils has delayed seeding.

Uncertainty surrounds the early-season U.S. wheat outlook for 1979/80 because weather adversities affect the crop right through harvest. Therefore, two weather-related crop year alternatives are used to indicate a possible range for the new crop. Under favorable growing conditions in the United States and throughout the world, the 1979/80 U.S. wheat crop year would feature: a near-record crop with supplies slightly above 1978/79; decreased export demand; a pickup in wheat feeding; increased carryover stocks; and some weakening of farm prices. Poor worldwide weather conditions feature: a U.S. crop slightly below 1978's; exports at a new record; dwindling stocks; total use at a new high; and a strengthening price picture.

Wheat disappearance during June 1978-March 1979 moved at a record-setting pace. Because of strong exports, likely to be the second largest on record, wheat use exceeded 1.7 billion bushels, about a tenth above last year. Total disappearance for 1978/79 will likely be a record, topping 2 billion bushels. Thus, yearend wheat stocks will decline for the first time in 5 years, and will be a fifth below a year earlier.

For seven consecutive months, average farm wheat prices have moved only a few cents around the \$3-per-bushel level. Not since the early 1970's have prices been this steady. This period of modest price fluctuation was largely influenced by the

large farmer-owned reserve stocks and producers' orderly wheat marketing. Despite a slowing export movement since January, prices have remained at their highest level in 4 years. Late season prices have approached the \$3.29-per-bushel release level, but as the 1979 winter wheat harvest draws closer,

prices may ease as buyers shift to a new-crop basis.

As of early May, crop conditions point to a decline in 1979 world wheat production. World trade is likely to remain large and U.S. exports are expected to continue near this year's level.

For the first time since establishing the farmer-held wheat reserve, national average wheat farm prices advanced above the \$3.29-per-bushel release level. Thus, on May 16, USDA released the more than 400-million-bushel wheat reserve. Until June 29, producers may, but are not required to, redeem their reserve wheat loans. On June 29, the Department will review the average wheat farm price to determine if the release authorization should remain in effect.

OUTLOOK FOR 1979/80

Increased Acreage Ups 1979 Winter Wheat Crop

Reflecting strong wheat prices last fall, farmers increased winter wheat acreage by 8 percent to 51.5 million acres. While acreage was up only 4 percent in major Hard Red Winter States, Soft Red Winter producers seeded a fourth more than the abnormally small area planted for the 1978 crop. Dry soil conditions slowed the good plant development needed before winter dormancy, but widespread snowcover and spring rains have restored subsoil moisture reserves. Pacific Northwest (PNW) White Winter wheat producers increased planting slightly but experienced abnormally high winterkill because of extreme cold and poor snowcover.

Based on conditions as of May 1, the 1979 winter wheat harvest was estimated at 1,391 million bushels, 11 percent above last year. Chances are 2 out of 3 that the final harvest will not differ from the May 1 forecast by more than 85 million bushels.

Spring Wheat Acreage Also Up; Wet Soils Delay Planting

Spring wheat growers indicated on April 1 their intentions to increase acreage 4 percent over last year. Durum farmers plan to seed 7 percent more. PNW producers nearly doubled spring White wheat plantings because of reseeded a relatively sizable acreage of winter White wheat that suffered severe winterkill. Hard Red Spring acreage, by far the largest of all spring wheats, will stay about the same as 1978—13.5 million acres.

Spring wheat seeding was far behind normal because of wet soils and cool temperature. By early May, about a fifth of the area had been seeded, compared to a norm of about 75 percent. These planting delays could substantially reduce Durum

and Northern spring wheat yields from last year's record high.

1979 Crop Likely To Be Larger

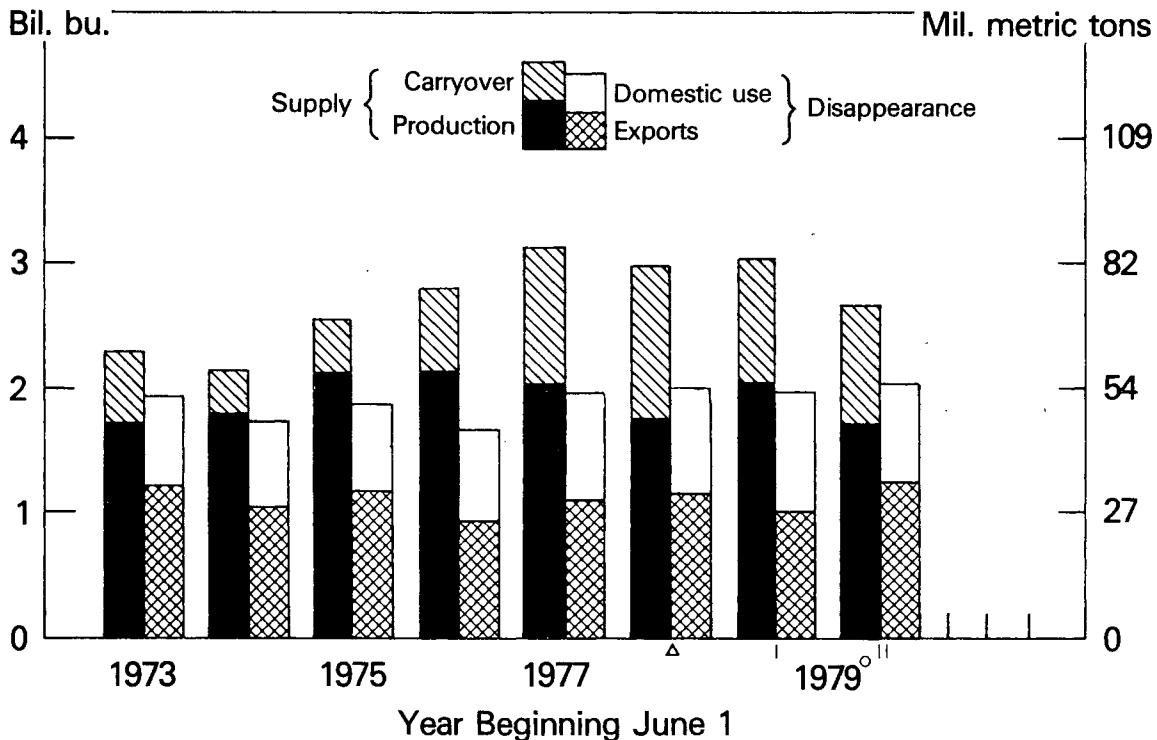

Excellent precipitation in the last few months has considerably brightened prospects for the total 1979 wheat crop. It appears that production will be up from last year's 1.8 billion bushels, but short of the 2-billion-bushel mark. Because of the lowest carryin stocks in 3 years, total 1979/80 supply could be down slightly from 1978/79 and substantially off the record 3.2 billion bushels of 1977/78.

Increased world wheat stocks levels, particularly in major exporting nations, will keep competition among exporters keen. U.S. wheat exports may be maintained near this year's level, but at this early date, the estimate ranges from 1,050 to 1,300 million bushels. Wheat feed use in 1979/80 should not greatly exceed this year's amount, but harvesttime developments (sprout damage and poor quality) often have an important bearing on this usage. Food use is projected to increase in line with recent growth trend, reflecting inclusion of more staple food products in diets. Wheat food products are competitively priced relative to other food items during this period of increasing prices. Total 1979/80 wheat use will probably again exceed the crop, and stocks would be moderately lower than the estimated 926 million bushels on June 1, 1979.

These supply/demand prospects suggest that wheat prices may follow 1978/79's pattern, with the average farm price up modestly from this year's estimated \$2.94 per bushel.

In some areas, the large farmer-held reserve stocks may tax storage capacity at harvest and be a pricing factor early in the season. But wheat producers have completed a relatively successful 1978/79 season of orderly marketing of their wheat

Wheat Supply and Disappearance

^ΔPreliminary. [◊]Projected. Alternative I and Alternative II.

USDA

Neg. ESCS 2117-79(5)

which, if followed in 1979/80, could aid in more steady price levels.

Impact of Weather Alternatives

Uncertainty always surrounds the early-season outlook for 1979/80 since weather adversities affect the crop until it is in the bin. While the current winter wheat crop is less vulnerable, the spring crop faces weather uncertainties for the entire growing season. However, since winter wheat comprises the bulk of the crop, uncertainty for the total 1979 U.S. wheat crop is relatively small.

Two supply-use alternatives are presented to underscore these uncertainties (table 1):

Alternative I assumes relatively high production worldwide resulting from generally favorable crop conditions. Under this situation, average yields could be moderately higher, resulting in a U.S. crop of around 2,075 million bushels, 15 percent above 1978's crop. This would bring supply levels to near the record of 3.2 billion bushels in 1977/78. Another large world crop (1978/79's was a record) would limit importers' demand for U.S. wheat and increase competition among major exporters.

Exports would be down, but still above the 1-billion-bushel mark.

Total disappearance would fall short of the crop and stocks would increase about 12 percent. This would force price levels within a range of \$2.80 to \$3.00 per bushel.

Alternative II assumes relatively unfavorable weather here and abroad. Some losses would occur to winter wheat but spring wheats would be hurt the most. Yields and harvested rates would decline, reducing the U.S. crop to slightly below 1978's crop. In turn, total supplies would decline by around 300 million bushels to their lowest level in 4 years.

A poor world wheat crop would increase import demand. Near-record large 1978/79 world wheat stocks would fill some of the added demand. U.S. exports could reach an all-time high of 1.3 billion bushels. Higher wheat prices would limit wheat feeding. Total disappearance would exceed the crop, resulting in a substantial stock drawdown. Such a drawdown would move farm prices upward to perhaps the \$3.70-\$3.90 range, considerably higher than the 1978/79 season's average of \$2.94 per bushel.

THE 1978/79 SITUATION

Wheat: Supply and disappearance

Item	June-March	
	1977/78	1978/79
	<i>Million bushels</i>	
June 1 stocks	1,112	1,177
Production	2,036	1,799
Imports	1	1
Total supply	3,149	2,977
Exports	886	1,027
Food	492	493
Seed	56	62
Feed	187	171
Total disappearance	1,621	1,753
April 1 stocks	1,528	1,224

in April 1 stock levels to 1.2 billion bushels compared with last April's record 1.5 billion. Inventories of Hard Red Winter wheat were down about 30 percent, while Soft Red Winter stocks are off over 60 percent. April supplies of Hard Red Spring and soft White wheat were about the same as a year earlier, while Durum wheat stocks were up about 15 percent.

More farm storage capacity, particularly in the Central Plains, and establishment of the farmer-held wheat reserve have resulted in sharp increases of on-farm stored wheat.

As of April 1, over half of the wheat supply was on-farm compared with 42 percent last April and 37 percent two years earlier. Over a third of total April stocks were in the farmer-held reserve or in Commodity Credit Corporation (CCC) inventory. Nearly 15 percent were 1978 crop outstanding loans.

Wheat Disappearance Banner High; Stocks Down

Wheat disappearance (June-March) moved ahead at a record-setting pace. Because of strong exports, wheat use totaled over 1.7 billion bushels, nearly 10 percent above last season. Even with the expected slowdown of exports for the remainder of the year, total 1978/79 wheat disappearance will be an all-time high of 2.1 billion bushels. Thus, year-end stocks will decline for the first time in 5 years. This strength in total wheat use caused a decline

Wheat Exports Heaviest in Six Years

June-March wheat export shipments were over 1 billion bushels. Not since the record 1973/74 export season have overseas loadings reached this mark in a 10-month period. Unusually large exportable supplies in major wheat exporting countries—EC, Australia, Argentina, and Canada—has caused a very competitive foreign trade situation, particularly during January-March, which cut into the strong U.S. early season export pace. January-

*1978/79 estimated. Includes flour and products in wheat equivalent.
USDA

Neg. ESCS 31-79 (5)

Wheat Prices Received by Farmers

USDA

Neg. ESCS 891-79 (5)

March shipments plunged 36 percent from an average monthly loading rate of 115 million bushels during the first half of 1978/79. Outstanding sales as of April 29 totaled 134 million. All this amount may not be shipped before May 31 so contract adjustments will push some loadings into the 1979/80 marketing year. Still, estimated 1978/79 wheat exports of 1.2 billion bushels will exceed last year and be the second heaviest on record. New crop year commitments are already close to last year's level, suggesting reasonably heavy shipments early in the new season.

Farm Wheat Prices Hold Firm

The average monthly wheat price received by farmers has shown little change for the last seven months. Since last October, the average farm value has moved only a few cents up and down from \$3 per bushel. Not since the early 1970's have prices been this steady. While there are a variety of wheat price levels throughout the United States, this pattern of narrow price fluctuations seems to hold true for all wheat classes except Soft Red Win-

ter (SRW). Extremely tight SRW supplies continually pressured prices upward. Producers seem to have established a market price goal and considered selling only when that goal was reached.

Holding wheat from the market has always been a marketing alternative for growers, but this strategy may have been more prevalent in 1978/79 which, in turn, aided higher and more firm price levels. To some extent, the construction of more on-farm storage over the past few years has been responsible for this marketing approach.

Since January, wheat market prices have held remarkably well in spite of a slowing export demand. Continued grain transportation problems, producer holding, dwindling available supplies, and the generally higher level of commodity markets have kindled moderate gains since January. Late season prices advanced to near the \$3.29-per-bushel reserve release level. Markets should ease as the 1979 harvest draws closer and buyers shift to a new-crop basis. With a good share of June 1 carryin stocks in the grain reserve, prices this spring and summer may be above those of a

year ago. Much depends upon export commitments in the early part of 1979/80 and the final outturn of the 1979 crop.

Wheat Loans Extended

Reflecting higher price levels, growers' use of the CCC loan program has been less than half of last year's heavy placements. By early May over

40 percent of these loans had been redeemed, leaving about 145 million bushels outstanding. Because the farmer-owned reserve program is not open to 1978-crop wheat, many outstanding loans would become due during the new crop harvest. However, as of mid-March, producers were given the opportunity to extend these loans for 6 months, thereby further easing downward pressure on wheat prices at harvest.

Wheat price support loan status, 1974-78 crops, as of May 2, 1979

WHEAT BY CLASS

HRW Stocks Dwindle, 1979 Crop Likely To Be Larger

This season's strong Hard Red Winter (HRW) exports have significantly reduced the large 1978/79 stocks. April 1 stocks are down about 230 million bushels from last year and nearly 900 million below the early season supply level. Of the nearly 575 million bushels of HRW stocks on April 1, over 55 percent were in the farmer-held reserve or owned by CCC, indicating tight supplies of readily marketable HRW. Total 1978/79 disappearance will far exceed the 834-million-bushel crop and pull the June 1 carryover down to around 415 million bushels, the lowest in 3 years.

HRW exports have softened since January but are expected to total around 625 million bushels for the year, 17 percent above 1977/78 and the third

largest on record. June-March exports totaled nearly 525 million bushels, and early May outstanding sales show another 70 million sold to foreign destinations for delivery by the end of the crop year—May 31.

HRW prices (Kansas City ordinary) have advanced after weakening during midwinter and have exceeded the \$3.50-per-bushel price of last fall. Prices could moderate in the remaining weeks of 1978/79 in response to slowing export sales and the outlook for a large 1979 crop. Conversely, some price firmness could come from producers having the option of extending maturity dates for 6 months on 60 million bushels of outstanding 1978 crop loans.

Based upon conditions as of May 1, the 1979 HRW crop could approach 930 million bushels,

almost 100 million above 1978's. However, combined with a reduced June 1 carryover, the 1979/80 HRW supply will be down about 15 percent from a year ago.

Hard Red Spring Exports Heavy

Export sales have been very strong this season with the year's total expected to exceed 220 million bushels, second only to the record shipments of 1973/74. Higher protein HRS wheats have been favorably priced with HRW for most of the marketing year, resulting in a pickup in sales to Western Europe and Middle East countries. Also, this year's large Chinese wheat purchase from the United States included 20 million bushels of HRS.

April 1 stocks of Hard Red Spring (HRS) totaled around 400 million bushels, about on par with a year ago. Over 50 percent of these stocks are in the 3-year farmer-held reserve or owned by CCC, compared with about 20 percent of last April's stock. Another 20 percent of the stocks are under loan.

HRS use during June-March was up nearly a third from the same period a year ago, mainly because of strong exports. Total 1978/79 disappearance should about match 1978's production, resulting in yearend carryover stocks about equal to the carryin level.

Although HRS cash market prices have shown some seasonal strength, they remain inverse to their typical premium relationship with HRW. This competitive situation may help further expand spring wheat export sales and domestic mill demand. But the approaching harvest of a larger 1979 HRW crop may forestall significant sales until the 1979/80 HRS/HRW price relationship becomes apparent.

As of April 1, HRS wheat growers intended to plant about the same acreage as in 1978. This would indicate producers' participation in the set-aside program may about match last year's. Soil moisture levels in the Northern Plains appear excellent for a good growing season, but planting lags far behind normal because of wet soils and cool temperatures. These seeding delays could reduce yields considerably below 1978's near-record level.

Durum Exports Strong: Supplies Large

Durum stocks on April 1 totaled around 105 million bushels, 15 percent above last year. As of March 31, 15 million bushels were under loan and 11 million in the farmer-held reserve.

Exports have also been very heavy through 1978/79, with shipments expected to surpass 1972/73's record level of 67 million bushels. Most of this flurry was the result of a strong world demand for Durum because of last year's smaller

Durum wheat: Planted acreage

State	1977	1978	1979
	<i>1,000 acres</i>		
Minnesota	85	100	95
Montana	230	300	290
North Dakota	2,600	3,300	3,700
South Dakota	145	195	185
Subtotal	3,060	3,895	4,270
Arizona	89	95	65
California	30	120	45
New Mexico	4	(¹)	(¹)
U.S. total	3,183	4,110	4,380

¹ Estimate discontinued in 1978.

world crop. Final export loadings could reach a new high of over 70 million bushels. Outstanding commitments for delivery in 1979/80 point to a continuing strong export schedule.

While 1978/79 domestic use is projected to remain on a growth trend, June-March mill grind barely kept pace with last year's rate, reflecting a mill grind shortfall due to transportation tieups during the winter. In addition, more Hard Spring wheat than usual may be spilling into the pasta flour market because of protein premiums.

Prices of No. 1 Hard Amber Durum (medium) Minneapolis moved up seasonally from \$3.60 in January to \$3.70 in late April. The large June 1 carryover and the prospects for increased production dim prospects for significant price rises in the coming year.

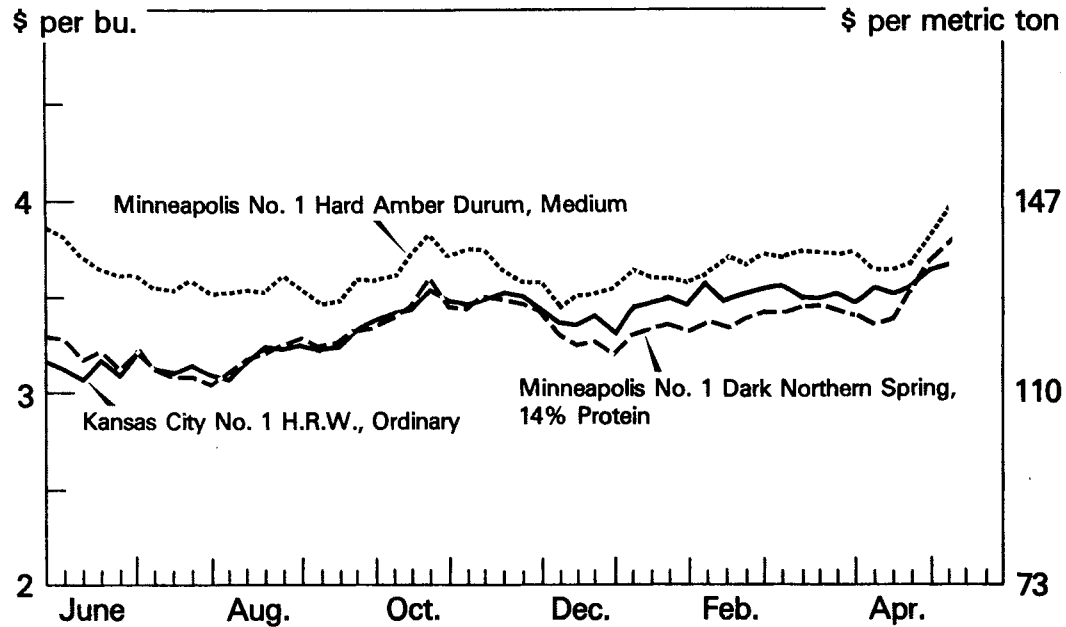

Durum growers intend to plant 4.4 million acres, 7 percent above last year and nearly 40 percent more than 1977's acreage. North Dakota growers, with 84 percent of total U.S. Durum acreage, were expected to increase 1979 seedings—12 percent more than a year ago. Plantings in other States are expected to decline, the largest coming in the "desert" Durum areas where California and Arizona farmers cut acreage by half. Spring seeding delays could substantially reduce yields below last year's record 33 bushels per acre.

SRW Stocks Down Sharply: New Crop Prospects Up

Stocks of Soft Red Winter (SRW) totaled about 45 million bushels on April 1. This is down 60 percent from a year ago and the lowest level since the extremely short supplies of 1973/74. Adding to this tight SRW supply situation are the 5 million bushels of reserve and CCC stocks not readily available to the market.

Reflecting the tight supply, June-March disappearance slipped nearly 30 percent below the pace of a year ago. Most of this decline occurred as

Cash Wheat Prices, 1978/79*

* Thursday price

USDA

Neg. ESCS 257a-79(5)

Cash Wheat Prices, 1978/79*

* Thursday price.

USDA

Neg. ESCS 257b-79(5)

export sales dropped 75 million bushels because of SRW's premium price levels. Total 1978/79 exports are expected to be at the lowest level in 5 years, or about half of the record 197 million bushels shipped in 1977/78.

Since January, SRW cash market prices rose 30 to 50 cents per bushel over Kansas City and Minneapolis hard wheat prices, and 10 to 20 cents over Portland soft White wheat. Chicago cash prices briefly shot above \$4 per bushel as March futures contracts were coming due and a shortage of deliverable stocks existed. SRW prices are expected to soften as the larger new crop eases the supply situation. However, the total 1979/80 SRW supply may not greatly exceed 1978/79's 273 million bushels. This suggests that next year's SRW price outlook may not differ much from this year. An estimated 25-percent increase in 1979 SRW acreage may produce a crop of around 275 million bushels. Minor winter damage, more spring fertilizing, and less acreage abandonment could increase the 1979 crop estimate.

White Wheat Exports Slow, Total 1979 Crop May Match Last Year's

White wheat stocks on April 1 totaled around 100 million bushels, down about a tenth from a year ago. Nearly 10 million bushels were under loan and 15 million in the 3-year reserve program.

June-March domestic use was up slightly from the 1977/78 level, reflecting early season feeding of sprout-damaged wheat. Mill grind was up mainly because of increased demand for low protein flour in the face of the tight supply and high price of SRW.

White wheat exports during June-March (155 million bushels) continue to exceed last year's pace by about 10 percent. The largest share of shipments was in the first half of 1978/79 trade year when the United States was the sole source of major exportable soft wheat supplies. By the middle of the marketing year, competition from the large wheat crop in the Southern Hemisphere began to temper U.S. export shipments. Since January, White wheat exports have slipped over 30 percent below the same period in 1977/78. Delays in shipments to Iran caused some of this decrease. Still, commitments as of early May indicate 1978/79 White wheat exports may slightly exceed last year's 174 million bushels.

Strong export demand and producer holding have maintained Portland White wheat prices in a narrow range around \$3.70 per bushel for most of this season. This price picture is likely to continue for the remainder of the marketing year with new export bookings expected to be light, but May 1 indications of a smaller 1979 winter white crop will pressure price advances.

Last fall, Pacific Northwest (PNW) wheat farmers seeded about 4 percent more White winter wheat. However, severe winter cold during periods of no snowcover caused above-normal freeze losses to winter wheat fields. Growers are expected to reseed these acres to spring White wheat varieties. Overall, 1979 White wheat planted acreage (Western, Eastern, and Spring) should be up about 20 percent, but the effect of heavy reseeding in the PNW will reduce this percentage. Conditions as of May 1 indicate lower yields in the PNW will also reduce total 1979 White production prospects.

WORLD WHEAT OUTLOOK

Production Projections for 1979

World 1979 wheat output is projected under two alternatives—generally favorable and unfavorable worldwide crop conditions. World wheat production under the former would be slightly down from last year's record 437 million metric tons and, under the latter, would be slightly above 1977/78's short crop of 382 million tons (table 1†).

Early developments suggest that world production may decline. Winter seedings were below intentions, especially in north European USSR, and wet weather delayed fall plantings in Eastern Europe. However, the reduced winter seedings in USSR and Eastern Europe will be offset by increased sowing of spring wheat and barley. In Western Europe, except France, seeding progress was good; however, France's wheat crop is forecast

to be down 4 million tons from 1978's 21.1 million tons due to retarded germination and frost damage. Spring seeding in the USSR and Europe is getting off to a very slow start due to wet and cold weather.

In China, some drought areas have received rainfall, but some parts of eastern and central China are still dry. Recent rainfall in the north improved prospects considerably for winter grains, especially winter wheat. In India, a record crop is likely for the fourth consecutive year.

World Wheat Use Slightly Up; Trade To Remain Strong

World consumption is projected to increase about 1 to 3 percent because of increased

Wheat: World wheat supply and distribution, marketing years 1970-79¹

population and growth in real income in the developing countries.

World wheat trade may equal or exceed this year's 72 million tons, but U.S. exports are forecast to decline because of large supplies held by major competitors. Some of the developments likely to affect the world wheat market:

- Export competition from Australia and Canada will continue strong because of record exportable surpluses.
- Canadian wheat production is expected to increase marginally in 1979. Transportation difficulties that frequently delayed deliveries to export terminals during last season may gradually be remedied in the coming year. Exports are expected to increase about a million tons in 1979/80 to over 15 million tons.
- Australia's wheat production is likely to be down sharply from 1978's extraordinary 18-million-ton record. Because of large stocks, the Australian Wheat Board will encourage exports at capacity levels. Australia's wheat exports may approach 11 million tons in 1979/80, up sharply from the previous year's 6.6 million tons.
- The European Community should end the 1978/79 marketing year with relatively high wheat stocks—over 8 million tons. However, with an expected smaller 1979 crop, EC wheat exports are not expected to reach this year's estimated 9.4 million tons.
- Import demand may increase, particularly in developing countries, resulting from possible reduced crops, increased population, and higher disposable incomes.

RYE HIGHLIGHTS

The bumper rye harvest in 1978 has resulted in extremely large supplies hanging over the marketplace. April 1 stocks were double a year earlier. For most of the season, prices of No. 2 rye at Minneapolis have remained steady within a narrow range of \$2.30-\$2.40 per bushel. Early May

prices were almost \$1 below a year ago, while Chicago Soft Red Winter wheat prices are running \$1.35-\$1.40 above rye.

Despite the low price level relative to all wheat classes, total rye disappearance does not show any significant increase. Indicated rye feed use has

gone up only 15 percent while supplies are nearly 40 percent above a year ago. Yearend rye stocks will be the highest in five years.

1979 Rye Crop May Be Up

Last fall, growers seeded 3.1 million acres of rye for all purposes, up 3 percent from 1978 and the largest acreage since 1973. Moisture conditions in the northern rye-growing areas are excellent, while added spring rains have improved prospects in the South.

Of course, 1979's production is predicated on total acreage harvested for grain. Major grain-producing States—Minnesota and North Dakota—reduced plantings while South Dakota, Georgia, and Nebraska increased seedings. Low rye prices and high livestock prices are likely to lead to more rye acreage grazed in 1979, limiting the area harvested for grain.

JAPANESE AND WESTERN EUROPEAN DEMAND FOR U.S. WHEAT

By P. Gallagher, M. Bredahl, and M. Lancaster

ABSTRACT: This is the second of two articles on the foreign market for U.S. wheat. The previous article contained a discussion of important trade policies and an analysis of demand in developing countries. This article contains an analysis of the demand in two major developed country markets: Japan and Western Europe.

KEYWORDS: U.S. wheat exports, developed countries, price and income elasticities.

Japan

The Japanese Food Agency, a government monopoly, fixes prices on the purchase and sales of wheat. Imported and domestically produced wheat is sold through the Agency at established prices. With the internal Japanese prices generally well above world levels, this results in a gain in government revenue on imported wheat. Japanese farmers' wheat prices are supported at a level above the world's, which tends to favor internal rice consumption over wheat consumption.

The Food Agency's influence on the country's internal supply and demand circumstances has been substantial.¹ The Agency's resale price of wheat (in real terms) has been steadily declining. Moreover, they discouraged domestic wheat production in the mid-sixties and early seventies by gradually reducing the nominal pegged farm level wheat purchase price (Wheat Associates, p. 108). Both of these factors tended to increase Japanese demand for imported wheat. The deflated resale price of wheat, Japanese wheat supplies, and U.S. exports to Japan are shown in the accompanying chart.

Since wheat is used mostly for human consumption in Japan, consumer demand theory provides the basis for specifying an import relation. Initial specifications included the controlled wholesale prices of wheat and rice, deflated by the Japanese consumer price index. An index of real per capita consumption expenditures

was used as a measure for income. Population was taken into account by stating values in per capita terms.²

Four results emerged from a wide variety of preliminary regressions. The effects of rice prices either had the wrong sign or a low t-value. Additionally, all specifications showed a reasonable, significant, negative income response—a result that is in contrast to some previous research on Japanese wheat consumption.³ Preliminary examination of data suggested that the 1971 West Coast dock strike had a substantial influence on wheat exports to Japan. Measures of dock strike length improved the R^2 substantially without altering the significance and coefficient estimates for other explanatory variables. Also, preliminary analysis indicated that supplies in competing countries do not exert a statistically significant influence on Japanese imports of U.S. wheat.

The relatively simple relationship between U.S. exports to Japan and (1) the wheat resale price,

²A recent study of Japanese wheat consumption employs a similar specification. Takayama, *et al*, report a per capita consumption equation which depends on the real resale prices of wheat and rice.

³Schmitz and Bawden (1971) give estimates of wheat food income elasticities for developed countries. Their estimates suggest that wheat is an inferior good in all developed countries except Japan. Takayama concluded that income is an insignificant explanatory variable. Another study of Japanese demand by Greenshields extended a preliminary report of the findings in this study. Utilizing Takayama's specification with a short time series (1960-74), the estimated income response was negative and significant. These results are not surprising in light of Japan's post-war economic growth.

¹For a review of some recent developments in Japanese wheat and rice policies, see Coyle

USDA

Neg. ESCS 73-79 (5)

(2) own supply, (3) real income, and (4) dock strike variable was selected as the "best" (see table 1). U.S. exports to Japan are relatively responsive to the wheat resale price, with an own price elasticity near -1.0. The income variable is negative and marginally significant, indicating that wheat is likely an inferior good in Japan.

Western Europe

For more than a decade, wide fluctuations in imports from the United States have characterized the West European wheat market. It is likely that policies of the dominant European Community (EC) have contributed to this instability. Wheat prices within the EC are insulated from world prices by means of a variable levy on imported wheat. A minimum import price (threshold price) is established for each marketing year. A levy in the amount of the difference between the threshold level and c.i.f. wheat prices is collected on imported wheat. The levy is adjusted daily to offset changes in the c.i.f. price. This practice assures that wheat does not enter the EC at less than the threshold price. Threshold price policies have achieved a basic EC objective: domestic production has been increasing and imports from outside the EC have simultaneously declined.

In fact, EC wheat production has expanded to the point where surplus disposal activities have been enacted. Farmers were subsidized for feeding wheat to livestock throughout the sixties and the early seventies. In addition, subsidies were granted for exporting wheat outside the EC. These latter

policies have made internal demands dependent on fluctuating government subsidy rates. And as a result of extensive wheat feeding, internal demands are also dependent on cycles in the feed-grain and livestock economies (Hauseman; Hudson; Friend).

Further complexity is added to the analysis by potential instability in the United States' share of the West European import market. There are, however, well defined periods of structural stability. The EC was established in 1962, but members were allowed to set threshold prices independently through 1966. Only after 1966 were all countries subject to uniform threshold levels. Thus, it is a reasonable hypothesis that coefficients in the share relation changed after 1966. It is also plausible that the United States' share of the West European market may have changed in 1972. Border compensation payments, which made intra-Common Market trade more profitable, were initiated at that time.

Attempts to directly estimate an equation for U.S. exports to Western Europe resulted in very limited success. Better results were obtained by estimating separate food and feed demand equations and a relationship for the U.S. share of this market. Implications for the U.S. exports were obtained by algebraic combination of these relationships.

Factors determining the feed demand for a grain are the price of the grain and substitute grain prices along with livestock population and prices of livestock (Womack). In the EC, wheat and corn are subject to the variable levy policy, so threshold prices for these commodities are the relevant variables. In this study, the wheat threshold price was adjusted by the subsidy rate for wheat feeding. In contrast to controlled wheat and corn prices, free trade in soybeans prevails throughout most of

West Europe. Wheat feed demand should be influenced by world soybean meal prices because both commodities are sources of protein. Thus, U.S. soybean meal prices are also included as an explanatory variable. The animal unit and livestock price indices are constructed from country data for the original six countries of the EC and the United Kingdom. These countries account for over ninety percent of West European wheat feeding.

Results shown in table 2 confirm the significance of feed grain prices in explaining Western Europe's wheat feed demand. The estimated coefficients for wheat, corn, and soybean prices are all significant at high confidence levels and all have correct signs.

The evidence that wheat feeding depends on the livestock economy is less conclusive. In preliminary regressions, livestock prices were insignificant and entered with incorrect signs. When livestock prices were excluded, the animal units variable had the correct sign and a reasonable elasticity (near 1.0), but the t-value was very low. The likely explanation for this low t-value is the high intercorrelation ($r=.967$) between the animal units index and the corn threshold price.

In other studies, income and population were the principle determinants of wheat food demand for individual European countries (Schmitz and Bawden, p. 23). In table 3, wheat food consumption in Western Europe is related to an index of regional per capita consumer expenditures. These results indicate that wheat, with an income elasticity of $-.233$, is an inferior good in the region. An \bar{R}^2 of $.876$ indicates a relatively good fit for this simple relationship. Threshold prices of wheat were also used as an explanatory variable, but were found to have virtually no effect on food consumption of wheat.

A share equation for Western Europe was estimated using a relatively short historical period: 1966 to 1974. The first year of this period marks the beginning of a fully operating Common Market. In table 4, the estimated equation shows a strong relation between Western Europe's wheat

imports and U.S. exports to the region. The estimated coefficient for Z_{we} suggests that the initiation of border compensation payments in 1972 exerted a significant downward influence on U.S. exports to Western Europe.

Using the estimated marginal share relation along with the food and feed demand elasticities, weighted total elasticities for the region were computed (table 5). The first column in this table contains elasticities for wheat food and feed use, while the second column shows elasticities for the U.S. share of the West European wheat import market. These elasticities highlight the importance of several variables that are not normally associated with the Western Europe wheat trade. For example, a one-percent increase in the corn threshold price and soymeal price increases Western Europe imports of U.S. wheat by 2.2 and 0.4 percent, respectively. The threshold price for wheat, with an elasticity of -3.4, also has an important negative impact on Western European wheat imports of U.S. wheat.

Foreign Demand for U.S. Wheat—An Overview

This article, and the earlier one on LDC's, have reported factors which influence U.S. wheat exports in two different markets. The analysis of LDC demand emphasized the forces affecting consumer demand under the assumption of free trade and incorporated the influence of U.S. wheat export policies. Results suggested competition among major food grains (wheat, rice, and coarse grains) at the world levels and a positive response to LDC incomes. The measurement also indicated substitution between U.S. food aid exports and LDC commercial purchases. In contrast, demands in the developed countries are restricted by price-fixing policies in Japan and the EC. Other important influences were also measured for this smaller but more complicated segment of the

export market; the depressing influence of income growth and the effect of West European wheat feeding were analyzed.

The relation between world wheat prices and LDC purchases from the United States suggests that adjustments in foreign consumption and purchases from the United States play a role in dampening the price fluctuation that accompanies changes in market conditions. However, such adjustments do not occur in Japan and Western Europe since prices are set by these governments. The wheat price elasticity for U.S. exports would be larger if free trade prevailed in Japan and Western Europe, perhaps twice the elasticity under existing policies.

The results also carry implications for the longer run outlook. In particular, income growth in foreign countries tends to alter the composition of foreign wheat sales. Rising incomes in LDC's tend to expand wheat purchases from the United States while income growth in Japan and Western Europe reduces wheat demand and purchases from the United States. However, equal percentage income growth in importing areas would probably expand U.S. wheat exports—the income elasticity is large and positive in LDC's but small and negative in Japan and Western Europe.

Table 5—Internal and import elasticities for wheat, Western Europe

Variable	Internal Elasticity	Elasticity of Western European Demand for U.S. wheat
Population	1.000	6.848
Income	-0.233	-1.596
Wheat threshold price	-1.594	-3.396
Corn threshold price .	1.038	2.212
Animal units	0.996	1.598
Soymeal price	0.187	0.398

1/ Alternative I assumes relatively favorable worldwide crop conditions; Alternative II assumes relatively unfavorable worldwide crop conditions. 2/ Includes transshipments through Canadian ports; excludes products other than flour. 3/ Production data include all harvests occurring within the July-June year shown, except that small grain crops from the early harvesting Northern Hemisphere areas are "moved forward"; i.e., the May 1978 harvests in areas such as India, North Africa, and southern United States are actually included in "1978/79" accounting period which begins July 1, 1978. 4/ "Bunker weight" basis: not discounted for excess moisture and foreign material. 5/ Utilization data are based on an aggregate of differing local marketing years. For countries for which stocks data are not available, (excluding the USSR) utilization estimates represent "apparent" utilization, i.e., they are inclusive of annual stock level adjustments. 6/ Stocks data are based on an aggregate of differing local marketing years and should not be construed as representing world stock levels at a fixed point in time. Stocks data are not available for all countries and exclude those such as China and parts of Eastern Europe; the world stock levels have been adjusted for estimated year-to-year changes in USSR grain stocks, but do not purport to include the entire absolute level of USSR stocks.

Weights, Measures and Conversion Factors

Bushel weights:

Wheat & soybeans = 60 lbs.
Corn, sorghum & rye = 56 lbs.
Barley (grain) = 48 lbs.: malt = 34 lbs.
Oats = 32 lbs.

Bushels to metric tons:

Wheat & soybeans = bushels x .027216
Barley = bushels x .021772
Corn, sorghum, rye = bushels x .025400
Oats = bushels x .014515

1 Metric ton equals:

2204.622 lbs.
22.046 hundredweight
10 quintals

1,000 kilograms

36.7437 bushels wheat or soybeans
39.3679 bushels corn, sorghum, or rye
45.9296 bushels barley
68.8944 bushels oats

Area:

1 Acre = .404694 hectares
1 Hectare = 2.4710 acres

Yields:

Wheat = bushels per acre x 0.6725 = quintals per hectare
Rye, corn = bushels per acre x 0.6277 = quintals per hectare
Barley = bushels per acre x 0.5380 = quintals per hectare
Oats = bushels per acre x 0.3587 = quintals per hectare
